# GLOBAL INCREASE OF TEMPERATURE - WINTER MONTH (2 m above surface)

biggest changes

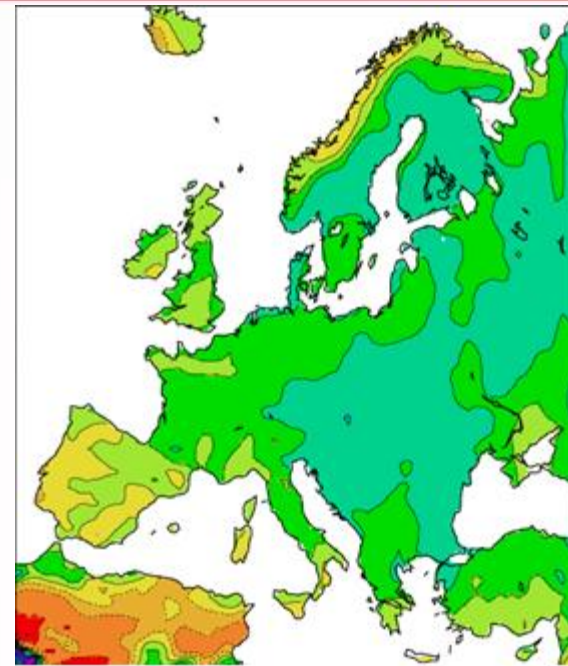

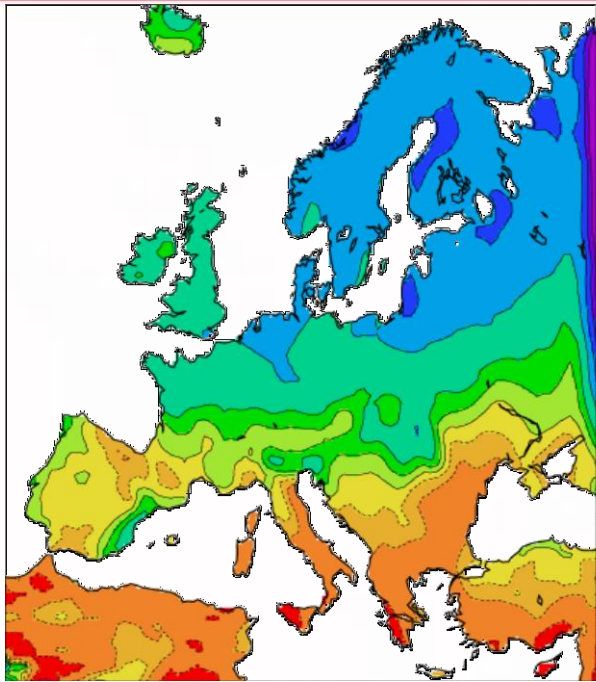

smallest changes

*Changes from 1961-1990 to 2071-2100.*

Rosby Centres scenarios based on global simulations from Hadley Center in Great Britain and Max Plank Institute for Meteorology in Germany.  
A2- and B2-scenarios emission scenarios from United Nations climate panel

# CLIMATE CHANGE – PRECIPITATION – WINTER MONTH

biggest changes

smallest changes

Changes from 1961-1990 to 2071-2100

Rosby Centres scenarios based on global simulations from Hadley Center in Great Britain and Max Plank Institute for Meteorology in Germany.

A2- and B2-scenarios emission scenarios from United Nations climate panel

# EXPECTED IMPACTS ON WINTER MAINTENANCE

## short term

- construction of winter budgets (*budget constraints, citizens expectations*)
- definition of appropriate contracts  
(*global amount ? number a winter operations ?*)
- de-icers managements (*consumption, storage conditions, tons ordered, late order, emergency situations*)
- sustainable considerations (*dissemination into the environment, local consequences,*

## long term

- investments on winter tools (*modularity of vehicles*)
- relevance of global RWIS
- development of tools dedicated to extreme, and sudden events
- manpower management (*massive retirements, loss of experience, training of winter staff*)

# CLIMATE CHANGE EFFECTS ON WINTER MAINTENANCE

*(literature)*

---

- decrease in the number of frost days,
- decrease in the amount of snow precipitations,
- mild winters, and more humid ones,
- decrease in winter maintenance,
- decrease in the number of very cold days.

Variations very heterogeneous,

Function of regions (close sea shore, altitude, ...),

Occurrence of climate change on more regions as time goes,

Projections over extreme events too difficult to be properly considered

# CLIMATE CHANGE IMPACTS ON INFRASTRUCTURES

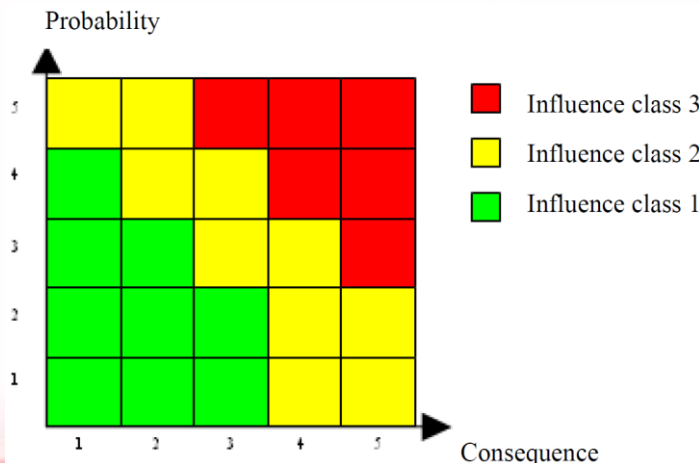

## Necessity to establish risks analysis grids

*Changes in precipitation and flow*

*Changes in temperature.*

*Changes in wind*

*Changes in sea level*

Effect of climate change and extreme weather events	Sweden	Norway	Finland	Denmark	Iceland	Faroe Islands
<b>Changes in precipitation and flow</b>						
Bigger landslides	Yellow	Red	Green	Green	Yellow	Green
Roads and bridges washed away	Yellow	Red	Yellow	Yellow	Green	Yellow
Flood	Yellow	Red	Yellow	Yellow	Yellow	Green
<b>Changes in temperature</b>						
Wear of pavements	Yellow	Yellow	Yellow	Yellow	Green	Green
Deformation of road construction	Yellow	Yellow	Yellow	Green	Green	Green
Winter transport on frozen roads	Red	Yellow	Red	Green	White	Green
Break down of concrete constructions	Yellow	Red	Yellow	Green	Green	Green
Icing of bridges	Green	Yellow	Green	Green	Green	Green
Temperature effect on bridges	Green	Green	Green	Green	Green	Green
Winter service	Yellow	Red	Yellow	Yellow	Green	Green
Falling stones	Green	Red	Green	Green	Yellow	Green
<b>Changes in wind speed</b>						
Big bridges and other vulnerable places	Green	Green	Green	Yellow	Yellow	Green
A lot of fallen trees over the road after a storm	Yellow	Yellow	Green	Green	White	White
Closing of high mountain roads	Green	Red	Green	White	Yellow	Green
<b>Changes in sea level</b>						
Tunnels	Yellow	Yellow	Yellow	Yellow	Green	Green
Roads	Green	Yellow	Red	Green	Yellow	Green
Ferry births	Green	Yellow	Red	Green	Yellow	Green

**Temperature**

**Potential Impacts**

**Vulnerable Element and Design Parameters**

Climate Event	Potential Impacts	Vulnerable Element and Design Parameters
Temperature	<p>rise in annual temperature will increase the deterioration rate of pavements will decrease pavement stiffness. Further increase in temperature will lead to permanent deformation of bitumen binder resulting in rutting and tension strain at the bottom of the pavement resulting in fatigue life.</p>	<p>Surface aggregate requirements, frost susceptible design.</p>
Frost thaw	<p>Increased number of frost thaw cycles in pavements will affect surface wear. Driving conditions will be affected. It will cause higher frequency of thawing and increased seasonal degradation.</p>	<p>Surface aggregate requirements, frost susceptible design.</p>
Rainfall and precipitation	<p>Intensity of summer and winter precipitation can create floods and with increased erosion and scouring as results. Probability of extreme weather events will increase. Driving conditions and visibility will be affected. Water characteristics will be affected and wear due to higher frequency of rain will increase. Driving conditions and visibility will be affected. Water content in unbound layers increases causing softer layers with lower permanent deformation.</p>	<p>Flood estimation analysis, return periods, design discharge, high flood level, river bank protections, drains size and shape. Slope protection. Design of base and subbase layers and material selection.</p>
Storms and storm surges	<p>Increased rainfall can create flooding and inundation on road causing erosion and disrupt traffic safety. It can affect emergency evacuation as well as traffic signs and other road furniture.</p>	<p>Drainage capacity enhancements, increased height of road embankments. Wind load on road sign. Structural design, foundation.</p>
Sea level rise	<p>Sea level rise will affect coastal roads. They may need to be realigned or elevated in some areas.</p>	<p>Protection walls and berm – breakwaters, realignment of road sections, edge strengthening.</p>

# CONCLUSIONS – ROAD CONSTRUCTION

---

- The main climate factors that affect pavement performance are temperature, water (moisture content) and frost thaw.
- A mechanistic empirical approach can predict performance of pavement structures. However, the accuracy of the method needs be improved.
- Model describing the temperature dependency of material behaviour are working quite satisfactorily.
- Moisture content (MC) within the pavement structures varies in time and space. MC has a great impact on the material behaviour of unbound granular material and soils and is therefore affecting the pavement performance. Enhanced knowledge is needed to improve our understand of how water is affecting the pavement structure.
- Seasonal variation and frost thaw cycles have great impact on the performance of pavements. No performance models are available that links frost thaw with performance.
